Trust

ABSTRACT

With the development of pervasive and ubiquitous computing, of IoT and personal devices, user-centric solutions will be the paradigm for most of the future applications. In this context, user-centric solutions must be proposed from deployment models to the content management. Obviously suitable Security, Privacy and Trust (SPT) solutions have to be proposed to ensure the smooth operation of systems and their straightforward managements required for a successful mass-user adoption. In this paper, we summarize the literature related to user-centric SPT scenarios and present a selection of the most recent advances in these areas.

1. Introduction

In future computing environments, due to the ongoing development of pervasive and smart technologies, movement towards user-centric solutions is paramount. The frameworks for everyday personal computing devices, including smartphones and smart cards, are becoming user-centric instead of issuer-centric [1]. User-centric solutions can target a wide range of applications, from individual devices communicating with other connected devices, through to data-sharing in cloud computing and open grids on very powerful computing systems. User-centric solutions address the devices and the ways in which they communicate, i.e. networks and end-user applications. The key factor in the success of user-centric solutions is the convenience for users; to achieve this Security, Privacy and Trust (SPT) in the user-centric ecosystem for any device must be ensured.

Until now, very few pieces of work related to user-centric SPT have been published in various journals and conferences; to cite a few in different domains:

- Castiglione et al. [2] propose secure group communication schemes in user-centric networks. They focus their attention on key predistribution for secure communications in those networks and introduce introduce Multi-PRSA, a novel scheme which efficiently extends and improves Polynomial Predistribution Random Subset Assignment Scheme (PRSA), in order to increase resilience against collusion attacks.
- De las Cuevas et al. [3] introduce a novel self-adaptive user-centric end-to-end system, named Multi-platform Usable Endpoint Security (MUSES) to securely manage Bring Your Own Device (BYOD) environment. MUSES considers users behavior in order to adapt, improve, and even increase the defined set of security rules. To do this, the system applies Machine Learning and Computational Intelligence techniques, being also able to predict future security incidences produced by these users.
- Gubbi et al. [4] present a user-centric cloud centric vision for worldwide implementation of Internet of Things in which associated challenges have been highlighted ranging from appropriate interpretation and visualization of the vast amounts of data, through to the privacy, security and data management issues that must underpin such a platform in order for it to be genuinely viable.
- Sánchez-García et al. [5] propose On-SiteDriverID, a secure authentication scheme based on Spanish eID cards for vehicular ad hoc networks, which has a user-centric design for road authorities point of view. They have conducted an evaluation of the proposal on simulated realistic VANET urban scenarios over a map of the city of Barcelona.
- Akram et al. [6] discuss two of the most widely accepted and deployed smart card management architectures in the smart card industry: GlobalPlatform and Multos and explain how these architectures do not fully comply with the User Centric Smart Card Ownership Model (UCOM) and GlobalPlatform Consumer-Centric Model (GP-CCM). They then design a novel flexible consumer-centric card management architecture designed specifically for the UCOM

https://doi.org/10.1016/j.future.2017.11.026
0167-739X/

and GP-CCM frameworks, along with ways of integrating the Trusted Service Manager (TSM) model into the proposed card management architecture whilst addressing the potential security issues.
- Vossaert et al. [7] present a user-centric identity management using trusted modules that tackles several privacy and security problems of current federated identity management systems (FIMs) and also adds extra functionality.
- Henze et al. [8] present User-driven Privacy Enforcement for Cloud-based Services in the IoT (UPECSI), a solution which takes a comprehensive approach to privacy for the cloud-based IoT by providing an integrated solution for privacy enforcements that focuses on individual end-users and developers of cloud services at the same time. UPECSI enables individual end-users to protect their potentially sensitive data before it is transferred to the cloud; empowers cloud service developers to efficiently integrate privacy functionality into the development process of a cloud service; and provides users an intuitive, adaptable, and transparent user interface which allows them to configure their privacy settings based on their individual privacy experience.
- Suriadi et al. [9] propose an extension of the existing federated single sign-on (FSSO) systems that adopts the beneficial properties of the user-centric identity management (UCIM) model. This new identity management system allows the users to control and enforce their privacy requirements while still retaining the convenience of single sign-on over a federation of service providers.
- Schreckling et al. [10] introduce Kynoid, a real-time monitoring and enforcement framework for Android. It is based on user-defined security policies which are defined for data-items. This allows users to define temporal, spatial, and destination constraints which have to hold for single items.
- Jin et al. [11] propose a unified access control scheme that supports patient-centric selective sharing of virtual composite Electronic Health Records (EHRs) using different levels of granularity, accommodating data aggregation and privacy protection requirements.
- Frangoudis et al. [12] focus on the provision of secure, user-centric voice services and explore their potential performance-wise, by designing a VoIP communications scheme tailored to open-access wireless environments.

The aims of this special issue being to gather and foster researches on this key topic of user-centric solutions, authors have been invited to submit original research papers on the state of the art, latest results and advances in SPT solutions for user-centric devices, network and applications, highlighting trends and challenges. Topics of this special issue included:

- Security, Privacy and Trust of:
  - User-centric Devices (Smartphones, PDA, RFID, Sensors, Smart Cards, Smart Cameras, Smart Objects),
  - User-centric Networks (Mobile Ad hoc Networks, M2M Networks, Urban Networks, Wireless Sensor Networks),
  - User-centric Applications (Cloud Computing, Data Provenance, Smart Grids, Smart Homes, Healthcare, Smart Spaces, Convergent Pervasive and Smart Environments);
- Technologies used to enhance Security, Privacy and Trust in User-centric solutions (NFC, IPv6, TPM);
- Societal issues related to Security, Privacy and Trust in User-centric solutions (HCI, User interactions).

After a rigorous review process, among the 73 very high quality submissions received, only 18 papers have been accepted for publication in this issue.

2. Content of this issue

In this special issue, the accepted papers are either related to domains of application, like finance or healthcare, either they are dealing with malware detection and security of mobile applications. Some selected papers are related to users' privacy or to secure resource/data-sharing solutions whereas few others address miscellaneous close topics.

2.1. SPT in financial domain

The first paper, "Proactive user-centric secure data scheme using attribute-based semantic access controls for mobile clouds in financial industry" by Qiu et al. [13] proposes an approach to proactively protect financial customers privacy information using Attributed-Based Access Control (ABAC) as well as data self-deterministic scheme.

The second paper, "Evaluation of transaction authentication methods for online banking" by Kiljan et al. [14] studies the online banking authentications in a user-centric context and proposes to extend an existing mechanism which quantifies accessibility, memorability, security and vulnerability characteristics, with aspects related to the feasibility dimension of secure usability of transaction authentication methods.

The third paper, "Secure and anonymous decentralized Bitcoin mixing" by Ziegeldorf et al. [15] proposes CoinParty, an efficient decentralized mixing service that allows users to reestablish their financial privacy in Bitcoin and related cryptocurrencies. Through a novel combination of decryption mixnets with threshold signatures, CoinParty takes a unique place in the design space of mixing services, combining the advantages of previously proposed centralized and decentralized mixing services in one system.

2.2. SPT in healthcare domain

The fourth paper, "On the design and analysis of protocols for Personal Health Record storage on Personal Data Server devices" by Belyaev et al. [16] proposes a new architecture, namely Personal Data Server (PDS) overlay, where the electronic Personal Health Records (PHRs) data is stored on a set of Secure Portable Tokens (SPTs, *i.e.* cheap, portable, and secure devices combining the computing power and tamper-resistant properties of the smart cards and the storage capacity of NAND flash memory chips and being able to act as a PDS) that are under the control of individual users. A formal analysis is also provided to ensure the correct behavior of the protocols used in PDS overlays.

The fifth paper, "A robust and anonymous patient monitoring system using wireless medical sensor networks" by Amin et al. [17] proposes an architecture for patient monitoring healthcare system in wireless medical sensor networks and designs an anonymity-preserving mutual authentication protocol for mobile users. The AVISPA tool is used to simulate the proposed protocol and demonstrates it resists the existing well known attacks.

2.3. SPT for malware detection and mobile applications

The sixth paper, "Owner based malware discrimination" by Han et al. [18] introduces the relativity issue of discrimination technique and proposes a malicious software discrimination model, named as Unlimited Register Machine of Owners (URMO) which includes analyzing and defining operations and objects as two elements of discrimination, introducing the concept of owner to give a reference to malicious signature, and comparing the model of Unlimited Register Machine (URM) with URMO to explain the origin of false positive and false negative.

The seventh paper, "Risk analysis of Android applications: A user-centric solution" by Dini et al. [19] presents a framework, called Multi-criteria App Evaluator of TRust for AndrOID (MAETROID), to evaluate the trustworthiness of Android apps by performing a multi-criteria analysis of an app at deploy-time and returning a single easy-to-understand evaluation of the apps risk level (*i.e.*, Trusted, Medium Risk, and High Risk) to help the user deciding on whether or not installing a new app.

The eighth paper, "Automatic security verification of mobile app configurations" by Costa et al. [20] proposes a novel technique for the security verification of groups of mobile app whose the approach relies on partial model checking (PMC) to extend the existing security guarantees to groups of applications.

The ninth paper, "You can't touch this: Consumer-centric android application repackaging detection" by Gurulian et al. [21] proposes an approach for detecting repackaged applications by taking advantage of the attackers reluctance to significantly alter the elements that characterise an application without notably impacting the applications distribution.

2.4. SPT for users' privacy

The tenth paper, "Your WiFi is leaking: What do your mobile apps gossip about you?" by Atkinson et al. [22] describes how mobile device apps can inadvertently broadcast personal information through their use of wireless networks despite the correct use of encryption and they present a remote, undetectable, detection mechanism to infer private user information through observation of encrypted app network activity.

The eleventh paper, "Time-based low emission zones preserving drivers privacy" by Jardí-Cedó et al. [23] presents a new user-centric Electronic Road Pricing (ERP) system for Low-Emission Zones (LEZs) that preserves the privacy of honest drivers and that is able to detect fraudulent drivers and revoke their anonymity.

2.5. SPT for resource/data-sharing solutions

The twelfth paper, "XSACd-Cross-domain resource sharing & access control for smart environments" by Fysarakis et al. [24] presents XSACd, a cross-domain resource sharing and access control framework for smart environments, combining the well-studied fine-grained access control provided by the eXtensible Access Control Markup Language (XACML) with the benefits of Service Oriented Architectures, through the use of the Devices Profile for Web Services (DPWS). Based on standardized technologies, this framework enables seamless interactions and fine-grained policy-based management of heterogeneous smart devices, including support for communication between distributed networks, via the associated MQ Telemetry Transport protocol (MQTT) based proxies.

The thirteenth paper, "AFT: Adaptive and fault tolerant peer-to-peer overlay - A user-centric solution for data sharing" by Poenaru et al. [25] proposes AFT, an overlay that adapts to a changing number of nodes, which is resilient to faults and the foundation for an efficient implementation of a reputation based trust system. The AFT overlay is designed to be a solution for systems that need to share transient information, performing a synchronization between various components, like in mobile ad-hoc networks, M2M networks, urban networks, and wireless sensor networks.

2.6. Miscellaneous SPT of user-centric solutions

The fourteenth paper, "Trusted mobile computing: An overview of existing solutions" by Bouazzouni et al. [26] presents a comprehensive surveys of the hardware-based (Secure Elements, Trusted Platform Module and Trusted Execution Environments) and software-based (Virtualization Environments) solutions for trusted mobile computing.

The fifteenth paper, "A Sybil attack detection scheme for a forest wildfire monitoring application" by Jan et al. [27] proposes two different techniques for Sybil attack detection for a forest wildfire monitoring application. The first one is a two-tier detection technique which uses high-energy nodes operating at a lower level to detect forged identities of Sybil nodes. The second one is a residual energy-based detection technique which uses the residual energy of each node to detect a possible Sybil attack at the high energy nodes.

The sixteenth paper, "HB$^+$DB: Distance bounding meets human based authentication" by Pagnin et al. [28] proposes to mitigate the man-in-the-middle attack against HB+ protocol by using physical layer measures from distance-bounding protocols and simple modifications to devices radio receivers.

The seventeenth paper, "Full integrity and freshness for cloud data" by Jin et al. [29] presents the design, implementation and evaluation of such a secure storage system where confidentiality, full integrity and instantaneous freshness check are achieved.

The eighteenth paper, "A novel face recognition algorithm via weighted kernel sparse representation" by Liu et al. [30] proposes a novel face recognition algorithm called Weighted Kernel Sparse Representation based Classification (WKSRC) whose experiments on the AR database reveal, it is more effective than SRC, WSRC and KSRC in term of recognition accuracy and, especially, it has better ability to deal with the occlusion scene.

3. Conclusion

Security, privacy and trust in many aspects cannot be envisioned as solely technical problems. Individual users that interact with the modern technology, have to taken in as equal partners to build a holistic system that provides foolproof security, privacy and trust mechanisms. Therefore, there is an emerging trend in the technology sphere especially and information security particularly, of developing technical solutions that involve, and empower its users. This trend has the potential to solve not only the present challenges but also the future challenges posed by emerging technologies like IoT, autonomous systems (transports, cars, drones) and Artificial Intelligence (AI). This paper has charted a small sample of this trend and its potential for the future.

Acknowledgments

We would like to thank all authors who submitted their papers, and all the reviewers for their time and effort. Their thorough reviews and valuable comments enabled us to select the papers, and provide a high quality Special Issue. We would also like to thank the FGCS Editor-in-Chief, Professor Peter Sloot, and the Elsevier staff for their help and support that made this Special Issue possible. We hope this Special Issue will serve as a reference for many future research projects.
