Recepción: 14 de septiembre de 2006

Aceptación: 29 de noviembre de 2006

## Resumen

La valoración de la inversión en compañías nacientes de alto crecimiento no es tarea fácil, pues los ingresos esperados se generan en un futuro lejano y bajo gran incertidumbre. De acuerdo con métodos tradicionales de valoración como el Valor Presente Neto, el mercado parece sobrevalorar algunas de estas compañías. Ello se debe a que estos métodos tradicionales no tienen en cuenta tres elementos esenciales que determinan el valor en estos casos: el capital intelectual como el motor de la innovación, el poder de mercado por la expectativa de ingresos monopolísticos si se da la innovación y una opción real de crecimiento que puede ser ejercida en caso de éxito.

Este artículo aplica a una empresa de biotecnología el enfoque de opciones reales y destrucción creativa (Maya, 2004), el cual incluye estos tres determinantes del valor y logra explicar el alto precio que los inversionistas pagan por una acción de este tipo de empresas. Se demuestra que éste no es un caso de sobrevaloración sino de reconocimiento del alto potencial de crecimiento de empresas que se encuentran en sectores altamente innovativos.

## Abstract

The value of investments in high growth start-up firms is difficult to assess because payments are far in the future and their arrival is uncertain. Some of these firms may seem overvalued according to traditional methods, such as the Net Present Value, which fails to account for three drivers of value for highly innovative industries: intellectual capital as the engine of innovation, market power as the expectation of monopolistic power when innovating, and a growth option which may be exercised in the case of success.

<sup>1</sup> Docente e investigadora del departamento de Finanzas, Escuela de Administración, Universidad EAFIT.

This paper presents a case study on a biotechnology start-up and applies the Creative Destruction – Real Options approach (CD-ROA) (Maya, 2004) which takes into account all three drivers of value and is able to explain the high prices investors pay for shares of a company in this industry. It proves that such prices are not cases of overpricing but of recognition of the large growth potential of firms which are part of highly innovative industries.

**Palabras claves:** Valoración, opciones reales, biotecnología, destrucción creativa, procesos estocásticos de salto.

**Keywords:** Valuation, Real Options, Biotechnology, Creative Destruction, Jump-only Stochastic Process.

***“Deals have started trading on best-case scenarios”.***

*Fitzsimmons (Prudential Securities) after Gilead Sciences Initial Public Offering in 1992<sup>2</sup>.*

More than ten years after the comment above and motivated by a rally on Biotechnology market prices, Morgan Stanley advised its clients to invest in “high-quality, later-stage biotech names with top and/or bottom line growth” (WSJ, 2003). In general, the valuation of these companies appears to be overpriced in terms of traditional methods such as discounted cash flows. They require large investments in R&D, depend on the success of clinical trials and on Food and Drug Administration (FDA) decisions, and only a few of them show profits. Additionally, when these companies become public, their products are in early stages of development. Consequently, there is much uncertainty regarding their value.

Although the Biotechnology industry is more than twenty five years old –not an infant industry anymore–, the prices of companies in this industry still present high volatility<sup>3</sup>. This is evidence that investors’ attitudes towards biotech firms have fluctuated over the years, and not necessarily depending on general market behavior.

<sup>2</sup> Investment Dealer’s Digest (1992).

The distribution of returns on the Initial Public Offerings (IPO)<sup>4</sup> of two hundred biotechnology firms covering the period 1980-2003 exhibits a median of 6.61%, a mean return of 15.85% and is highly skewed to the right. Figure 1 shows the histogram of these returns. This is a representative sample of the industry in terms of the period it covers and the number of firms included<sup>5</sup>, meaning it comprises periods of time when the stock market was booming and in recession, and when the stock market for this particular industry was alternatively bearish and bullish. Furthermore, it is not just a case of success at the stage of their IPO since returns on the Nasdaq Biotechnology Index (NBI) from January, 1995 to August, 2006, were almost twice the returns of the S&P500 for the same period<sup>6</sup>.

How could some apparently high valuations in the Biotech industry be explained? Generally, the valuation of investments in start-up firms

<sup>3</sup> Average annual volatility of returns on the Nasdaq Biotechnology Index (NBI) from January, 1995 to August, 2006 is 37.5%.

<sup>4</sup> These returns are computed as the percentage change in the closing price over the offer price of the IPO. The sources of information on the offering price are Lexis-Nexis News and <http://www.BioSpace.com> (June 4<sup>th</sup>, 2003) For the closing price the source is <http://finance.yahoo.com> (June 18, 2003).

<sup>5</sup> The biotechnology industry was born at the end of the seventies and this sample includes more than 41% of the public firms in the industry by June 30, 2003.

<sup>6</sup> Annualized average daily returns on the NBI for this period were approximately 24% versus 13% on the S&P500.

Figure 1

in high growth businesses is difficult to assess because payments are far in the future and their arrival is uncertain. Some of these firms may seem overvalued according to traditional methods such as the Net Present Value, which fails to account for three drivers of value for highly innovative industries: intellectual capital as the engine of innovation, market power as the expectation of monopolistic power when innovating, and a growth option which may be exercised in the case of success.

The Creative Destruction – Real Options approach (CD-ROA) (Maya, 2004) takes into account all three drivers of value and is able to explain the high prices investors pay for shares of one of these firms. It proves that these prices are not a case of overpricing but rather of recognition of the large growth potential of firms which are part of highly innovative industries. Clearly, the biotechnology industry is one of such industries. This paper performs a Case Study applying the CD-ROA to a real biotechnology firm, Gilead Sciences Inc. For this purpose, I will begin by discussing the

characteristics of the industry, the technology, and the product, which allow me to use this approach on this particular case.

### 1. Biotechnology and antisense technology for drug discovery

The Biotechnology Industry Organization -henceforth BIO- defines biotechnology as “the use of the cellular and molecular processes to solve problems or make products. Included in this definition of the industry are the firms that use cells and biological molecules for applications in medicine, agriculture, and environmental management” (BIO, 2000).

This industry has become the focus of attention of politicians as well as investors because there are many expectations about its potential to improve the quality of life, increase agricultural productivity, and generate a safer environment. Also, from an economic point of view, it gets great attention due to its fast growth –the industry has more than quadrupled in revenues

and increased almost seven times in market capitalization since 1994<sup>7</sup>.

The larger group of biotech firms is focused on therapies for human diseases. Particularly, the deciphering of the human genetic code has pushed fast development of genetic drugs. There are two main categories of therapies based on this kind of drug: gene therapy which involves inserting new genes into cells to produce therapeutic proteins in the body and nucleic acid-based therapy or code blocking which switches off genes so that they stop making harmful proteins.

There are three principal strategies in the development of products for nucleic acid-based therapeutics: Antisense, Triplex, and Ribozyme technologies. Appendix A, Exhibit A1 gives a description of each one, its major therapeutic targets, and the name of the companies competing in each technological race. Of these three technologies, this paper focuses on the oldest one, the antisense technology, and the competition that takes place among the antisense firms to develop new drugs against HIV/AIDS<sup>8</sup>.

In 1980 AntiVirals Inc., now AVI BioPharma Inc., became the first antisense firm, but it was not until 1986, after Dr. Zamecnik published a paper showing that the antisense strand could interfere in the life cycle of the AIDS virus, when research on this technology really took off. Principally four companies started to compete on the development of antisense drugs

against viruses, having HIV/AIDS as their natural target. Gilead Sciences Inc. in 1987, Isis Pharmaceuticals Inc. in 1989, and Hybridon Inc. in 1990, joined AVI BioPharma Inc. in a technological race to discover the first antisense compound to fight HIV/AIDS.

HIV/AIDS captured the attention of the antisense companies because at the end of the eighties it had become a major worldwide epidemic<sup>9</sup>. AIDS is caused by the human immunodeficiency virus (HIV). By killing or damaging cells of the body's immune system, HIV progressively destroys the body's ability to fight infections and certain cancers. Since the epidemic began, more than sixty million people have been infected by the virus. HIV/AIDS is now by far the leading cause of death in sub-Saharan Africa, and the fourth biggest global killer. In 2001, the epidemic claimed about three million lives<sup>10</sup>.

With the aim of fighting HIV/AIDS, a group of scientists founded Gilead Sciences, Inc. in 1987. This company, located in Foster City, California, has focused its research on the development of antisense compounds against viruses, specifically HIV. Exhibit 2 shows the market price of its stock from the time of its inception up to its IPO. The last value of \$214.5 million is calculated based on the offer price for the IPO. The actual price achieved by the company was \$289.6 million, after a successful public offer which made an investment banker exclaim that "Deals have started trading on best-case scenarios". In what follows I apply the Creative Destruction-Real Options Approach (CD-ROA) (Maya, 2004) to explain why investors paid 35% more than the offer price for Gilead Sciences when it went public in January 22, 1992.

<sup>7</sup> <http://www.bio.org/er/statistics.asp> (August 31st, 2006).

<sup>8</sup> The antisense drug is a "synthetic strand of genetic material which replicates the second strand of the DNA double helix, called the antisense strand. It sticks to the mRNA like Velcro, and blocks the production of proteins. It is this process, much more precise and foolproof than the tentative way in which most current drugs cling to bad proteins, that hints at so much promise for these synthetic strands, which are known as antisense oligonucleotides, or oligos for short". "Antisense: A Drug Revolution in the Making", Business Week, March 5<sup>th</sup>, 1990.

<sup>9</sup> The first case of AIDS was reported in the U.S. in 1981.

<sup>10</sup> Report on the Global HIV/AIDS Epidemic 2002 [http://www.unaids.org/epidemic\\_update/report\\_july02/english/contents.html](http://www.unaids.org/epidemic_update/report_july02/english/contents.html) (June 16, 2003)

## 2. The valuation of Gilead Sciences Inc. based on the CD-ROA

---

Valuing Gilead Sciences on the basis of its passive NPV is inadequate. Such valuation does not account for the fact that this company is subject to a creative destruction process and for the real options it available to it, specifically a growth option which can be exercised if it succeeds in innovating. An approach like the CD-ROA can estimate the value of this firm in a more accurately way as is discussed in what follows.

Gilead Sciences (henceforth Gilead) is subject to a creative destruction process described by Schumpeter (1942) since it is in a patent race against Isis Pharmaceuticals Inc. (Isis), AVI BioPharma Inc. (AVI BioPharma), and Hybridon Inc. (Hybridon) to develop the first antisense drug against HIV/AIDS, in a way that the first innovating firm becomes a monopolist in the market. Immediately after that, another patent race starts where the next innovating firm takes the previous monopolist's market power away. Permanently, some value is created but, at the same time, some is destroyed.

This patent race is "memoryless" as coined by Tirole (1988), meaning that all the firms in the market start from the same point. Past R&D experience or expenses do not affect the result, only the current R&D expense is a determinant of the probability of success in innovation. The CD-ROA assumes a single expected innovation, a drug against HIV/AIDS in this case, produced by means of a single R&D technology, the antisense technology, by a profit maximizing firm. The cost function is assumed to be the same for all the firms involved in the patent race.

Another assumption of the CD-ROA is that innovation is always "drastic" in the sense that the product developed by the expected monopolist guarantees absolute market power

to the innovating firm. The discovery of an antisense drug for HIV/AIDS would be considered a drastic innovation since this technology is much more precise than most current drugs in the way they cling to bad proteins. As a result, it would not produce the unwanted side effects characteristic of current drugs.

In addition to the expectation of an exclusive market power that emerges in a creative destruction process, the CD-ROA accounts for another factor, a growth option, which also adds value to the firm. This option may be exercised in the case of innovation if the change in the firm's value is larger than the additional investments required for these purpose. The underlying asset to this option -  $S$  - is the current value of Gilead's research project without flexibility. This value follows a jump-only stochastic process since market risk is ruled out by the expectation of an exclusive market power, thus the only uncertainty this firm faces is the technological risk of innovating first or being defeated in the race.

Due to this technological risk, the underlying asset is subject to two independent sources of jumps. One occurs when the expected monopolist introduces a "drastic innovation" causing a proportional change in the asset's value equal to  $\zeta = (J - 1)S$ , meaning that when  $S$  jumps, its value changes to  $SJ$ . The other jump occurs when the challenger firm wins the race by innovating first or produces a "drastic innovation" which puts an end to the previous firm's monopolistic power. In this last case, the underlying asset's value will jump to a scrap value,  $SY$ , since once the firm is forced out of the market, the only alternative is selling its assets for their scrap value. Hence, the proportional change in the asset's value is  $\gamma = S(Y-1)$ . Immediately after that, it may participate in a new technological race which starts immediately after the challenger firm innovates.

Based on the above, S follows a jump-only stochastic process:

$$dS = (J - 1)S dq + (Y - 1)S d\pi \quad (1)$$

therefore,

$$d \ln S = (\ln J) dq + (\ln Y) d\pi \quad (2)$$

where

J : jump size in the case of innovation by the expected monopolist;  $\ln J \sim \phi(\mu, \sigma)$ ;

Y : constant percentage of scrap value when the challenger innovates;

dq: a Poisson process, which is equal to one with probability  $\lambda_m$  and zero with probability  $(1 - \lambda_m)$ .  $\lambda_m$  is the intensity of the Poisson process (expected number of drastic innovations);  $\lambda_m dt$  is the probability of innovation by the expected monopolist per unit time.

d $\pi$ : another Poisson process which is equal to one with probability  $\lambda_c$  and zero with probability  $(1 - \lambda_c)$ .  $\lambda_c dt$  is the probability, per unit time, of the challenger firm innovating.

Both,  $\lambda_m$  and  $\lambda_c$ , depend on the corresponding firm's level of investment in R&D -as a proportion of the total amount of investment required to producing and marketing the product- in the following way:

$$\lambda_i = \lambda(R\&D_i) = (R\&D_i)^{b_i} \quad b_i < 1 \text{ and constant}$$

meaning that the expected number of "drastic innovations" each firm can introduce in the market is a concave function of R&D, therefore, the probability of innovation increases by less as larger R&D investments are put in place. Firm i expends  $R\&D_i dt$  between time t and t + dt.  $b_i$  is a parameter that measures the efficiency of such investment.

If the value of S after innovating is greater than the value of the investment required to

produce and market the product, the firm will exercise its growth option, G. By doing so, it exploits the exclusive market power guaranteed by its monopolistic position. The amount of investment necessary to exercise the option is the exercise price, X. The value of G at t = 0 is equal to the present value of its expected payoff:

$$G_0 = e^{-rt} E_0 [\text{Max}(S_t (\lambda_m, \lambda_c) - X, 0)] \quad (3)$$

In a creative destruction process, the jump risk is non-systematic since it depends only on the technological uncertainty that surrounds the project and it affects the firms subject to this process exclusively. Being that the case, this risk may be diversified away (and therefore should not be priced by the market) by means of conforming a well-diversified portfolio which includes this project along with other assets (Ross, 1976). On the other hand, there is no market risk either since the firm has absolute market power, as explained above. In consequence, the appropriate discount rate for the option's expected payoffs is the risk-free rate, r.

If there is no innovation, the innovation is not drastic, or another firm wins the technological race, this firm may abandon the project and move on to a new project, a new patent race. The value of the firm, V, will be the sum of the project's value without flexibility represented by  $S(t=0)$  plus the value of the growth option  $G(t=0)$ :

$$V(t=0) = S(t=0) + G(t=0) \quad (4)$$

### Assessing CD-ROA Parameter Values for the Case of Gilead Sciences:

For S, the underlying asset price, I take the offer price for Gilead's IPO since it is set by an investment banker based on the valuation performed on the firm, which I assume was done, at that time, using traditional valuation

methods which do not account for flexibility. The offer price was \$15, thus the value of the company at that price, including the new shares issued in the IPO, was \$214,500,000<sup>11</sup>. However, the offer price usually includes a discount to attract investors which is typically 10%<sup>12</sup>, thus the value of Gilead would have been \$235.95 million.

X, the exercise price for the growth option, is the amount of additional investment in plant, equipment, and working capital necessary to produce the new drug. There is no information about an estimation of this amount for the industry. I found some evidence, however, from the same firm under study and from Agouron Pharmaceuticals, another biotechnology firm which was studied by Kellogg, Charnes, Demirer (2002).

In the case of Gilead Sciences, the production of Viread, its successful drug against HIV/AIDS, required an additional investment of 27% of the increase in revenues from 2001-2002 (See Appendix A, Exhibit A3.2: Gilead Sciences Balance Sheet and Exhibit A4.2: Consolidated Statement of Operations data). A similar percentage, 22%, was required by Agouron Pharmaceuticals when it started producing Viracept, the previously successful drug for HIV/AIDS. In the period 1997-1998, Agouron's total revenue increased by \$335 million requiring \$74 million in additional investment. (See Appendix A, Exhibits A5.1 and A5.2 for Agouron Balance Sheet and Consolidated Statement of Operations data). Based on the this evidence, an estimate for X of 25% of the expected additional revenues will

be used in this case. Kellogg, Charnes, Demirer (2002) cites data from Myers and Howe (1997) on expected revenues from new drugs as shown in the next table:

**Table 1**  
Expected Revenues from New Drugs

	Peak Annual Revenue	Probability
BREAKTHROUGH	1,323,920	10%
ABOVE AVGE	661,960	10%
AVGE	66,200	60%
BELOW AVGE	7,440	10%
DOG	6,620	10%
E [ REVENUE ]	239,714	

Myers and Howe (1997)

A drastic innovation corresponds to a breakthrough drug. Exhibit A6 shows the expected revenue generated by the sales of a breakthrough, and the additional investment required to produce it calculated as 25% of this revenue. The exercise price of the growth option is the present value of this investment: \$189.52 million.

In the CD-ROA, mainly two factors determine success in this technological race: the amount of R&D each firm is willing to invest and the efficiency of such an investment. Average industry values for these parameters are provided by Kellogg, Charnes, Demirer (2002)<sup>13</sup> where it is shown that, for the discovery phase, the average investment is \$2.2 million, therefore, the average ratio of R&D / X equals .0116. Also, a value of  $b = \frac{1}{2}$  was suggested by Darby, Liu, Zucker, (1999), therefore the probability of discovery is  $\lambda = (R\&D/X)^{\frac{1}{2}} = .1077$  per year, meaning that the average time to discover a drug is around ten years<sup>14</sup>.

<sup>11</sup> Appendix A, Exhibit A2 shows the number of shares issued by Gilead Sciences and the firm's value from its inception up to its IPO.

<sup>12</sup> Ivo Welch, a Finance Professor who has studied IPOs extensively, notes that the typical underpricing -the return from the offer price to the price when the market starts trading - is about 10%. <http://www.iporesources.org/lebaron.html> (Sept. 4th, 2003).

<sup>13</sup> They make assumptions based on previous work by Myers and Howe (1997), Office of Technology Assessment (1993), DiMasi et al. (1991), and Grabowski and Vernon (1994).

<sup>14</sup> Evidence showing that this is the average time required to discover a new drug is cited by Cochrane (2001), Schwartz (2002), and Kellogg, Charnes, Demirer (2002).

In order to compute the amount of R&D as a proportion of X for the firms participating in this race, I use the actual firm's expenses on R&D in 1992<sup>15</sup>. Table 2 shows the R&D / X ratio for each firm<sup>16</sup>. See Appendix A, Exhibits A7, A8.1, and A9 for the Consolidated Statement of Operations Data of Isis Pharmaceuticals Inc., Hybridon Inc., and AVI BioPharma Inc., respectively.

**Table 2**  
R&D Expenses

FIRM	R&D (R&D expenses / X)
Gilead Sciences Inc.	0.0720
Isis Pharmaceuticals Inc.	0.1261
Hybridon Inc.	0.0467
AVI BioPharma Inc.	0.0039
Total Challengers	0.1767

Clearly, the greater the amount of investment the expected monopolist is willing to make, relative to its challengers, the higher its probability of becoming the next monopolist. In this case, Gilead is investing more than Hybridon and AVI BioPharma combined, but less than Isis, giving this last firm an advantage in this race.

The other determinant of which firm will win a technological race is the efficiency of its investment in research. Measuring efficiency is a difficult task in general, but even more for start-up firms which usually are on early stages of development of their products. They do not show profits, revenues are very low, and sometimes they do not even have any patents,

as it is the case under analysis. However, two different ways to assess efficiency will be proposed next, keeping in mind that the subject calls for additional research.

The first methodology accounts for the number of patent applications filed up to the time of the IPO. It would be preferable to consider the patents approved since there is no guarantee that an application would become a patent. However, none of these firms had any patents approved at the time of this analysis. Before January 1992, Gilead and Isis had filed for ten applications each, Hybridon just for one, and AVI BioPharma had zero applications<sup>17</sup>. In the standard case, a  $b = \frac{1}{2}$  represents the average efficiency.<sup>18</sup> On the other hand, there are reasons to argue that the real competitors in this race were Gilead and Isis only. AVI BioPharma investments in R&D were very low until 1997<sup>19</sup> and Hybridon was recently founded in 1990. By January, 1992, only Gilead and Isis had expectations of filing an Investigational New Drug (IND) application<sup>20</sup>. According to this argument, and based on the number of patent applications filed by each company, both are equally efficient and  $b = \frac{1}{2}$  for both.

Another approach to measure the efficiency of R&D is computing the ratio of revenue to R&D expenses as it is shown in the next table<sup>21</sup>:

<sup>15</sup> The information the potential investor requires is the expected expenses on R&D next period by both the expected monopolist and its challenger. I use the actual value as a proxy for this value.

<sup>16</sup> There is no public information for Gilead Sciences in 1992. R&D expenses on that year were calculated based on 1993 data and adjusted to grow at the same average growth that this account showed in the following three years: 33.11%.

<sup>17</sup> U.S. Patent and Trademark Office (PTO). <http://www.uspto.gov>. (June 27, 2003).

<sup>18</sup> The standard case is when these firms invest the average amount of \$2.2 million in R&D in the discovery phase.

<sup>19</sup> See Exhibit 9.

<sup>20</sup> Isis filed the first IND application for an antisense drug – ISIS2105- in January 30, 1992. (PR Newswire, January 30, 1992). Gilead filed for GS504 in March, 1992 (Business Wire, March 19, 1992) and for GS393 in September, same year (Business Wire, September 23<sup>rd</sup>, 1992).

<sup>21</sup> This ratio is the Average revenue / Average R&D for the period 1993-1996 when public information is available for Gilead, Isis, and Hybridon. For AVI BioPharma, the ratio is computed as the average for the period 1995-1996 since public information is available only after 1995.

**Table 3**  
Revenue to R&D Expenses Ratio

FIRM	Gilead	Isis	Hybridon	AVI Bio Pharma
Revenue/R&D	0.40	0.54	0.07	0.03

Efficiency in terms of this ratio gives another argument to support that although apparently there were four firms competing in this race, the real competition was between Gilead and Isis since the ratio for Hybridon and AVI BioPharma is close to zero. Based on the ratio shown above for Gilead and Isis, it is clear that Isis' research was more efficient. If a Revenue / R&D ratio of 1/2 is taken as the average<sup>22</sup>, Gilead will be 20% less efficient and Isis 8% more efficient than the average case, therefore  $b(\text{Gilead}) = 0.55$  with  $\lambda m = 0.086$  and  $b(\text{Isis}) = 0.482$  with  $\lambda c = 0.116$ .

As for the other determinants of value, the drift rate for S is r, the risk-free rate. The interest rate on the 10-year Federal bond was 7.03% in January, 1992. This approach also requires data on the distribution of the size of the jump, J, where  $\ln J \sim \phi(\mu, \sigma)$ . As a proxy for  $\mu$  and  $\sigma$  I take the mean and standard deviation of the NBI in a period of ten years starting in November 1<sup>st</sup>, 1993, when  $\mu = 12.77\%$  and  $\sigma = 35.74\%$ .

Finally, for the scrap value, I assume 80%, meaning that when another company preempts the monopolist, this last one may still get some value by selling its assets and recovering at least 80% of their value at that time<sup>23</sup>.

<sup>22</sup> This ratio was 0.51 for Isis Pharmaceuticals in the period 1990-1992 (Exhibit 7) and 0.49 for Agouron Pharmaceuticals in the same period (Exhibit 5B). There is no information for Gilead in this period.

<sup>23</sup> In this case, the assets are mainly equipment with the newest technology, therefore, an assumption of an 80% scrap value would be appropriate.

### 3. Simulation and results

In order to value Gilead, I use the Monte Carlo method. According to (2), the stochastic process  $\ln S$  follows is:

$$d\ln S = (\ln J)dq + (\ln Y)d\pi \quad (5)$$

This process can be approximated by:

$$d\ln S = \ln \frac{S_t}{S_{t-1}} = (\ln J)dq + (\ln Y)d\pi \quad (6)$$

Using Monte Carlo, n paths of asset prices are simulated as follows:

$$S_t = S_{t-1} * e^{[(\mu - \frac{\sigma^2}{2}) + \sigma Z] * \text{Dummym}} * e^{[\ln Y] * \text{Dummymc}} \quad (7)$$

where Z is a normal random variable. Dummym is one when there is a jump J and zero otherwise. The probability of a jump J in a period of time dt is  $\lambda m dt$ . Then, Dummym will be one when the value of a simulated uniformly distributed random number is less than or equal to  $\lambda m dt$  and zero otherwise.  $\mu$  and  $\sigma$  are the mean and standard deviation of this jump J, a process that is assumed to follow a lognormal distribution. On the other hand, the probability of a jump Y is  $\lambda c dt$ . Dummymc is one when there is a jump Y and zero, otherwise, and it may be simulated in a similar way to Dummym. Y is assumed constant.

The n paths of S are simulated up to a time period T which covers the average time for a "drastic innovation" to take place in the industry. Whenever a Dummym equals one is found on each path, the asset price jumps. At that time, t, the firm decides to exercise the option depending on the size of the jump and the corresponding value reached by S(t). If this value is greater than the value of the exercise price (X) as defined above, the firm exercises

the option, and the option payoff is discounted at the risk-free interest rate. If the challenger innovates first or none of them innovate, the payoff from the option on that path is zero. The expected value of the growth option,  $G$ , will be the average of the present value of all these payoffs. The final value of the firm will be the sum of the project's value without flexibility –  $S$  ( $t=0$ ) – plus the value of the growth option  $G$  ( $t=0$ ).

Two different cases are analyzed in order to value Gilead. Exhibit 10 shows the parameter values used to simulate each case. If the race is defined between Gilead and Isis only, they are equally efficient in terms of the number of patent applications, but Isis is investing more in research. In this case, the value of Gilead should have been around \$286.26 millions. The other case measures R&D efficiency on the basis of the ratio of Revenue / R&D. Isis is more efficient and it also invests more than Gilead, resulting in a much lower value for Gilead of \$289.58 millions.

Gilead's investors actually paid \$20.25 for its shares in its IPO, which is 35% higher than the offer price and translates into a market value of \$289.6 millions, close to the previous two estimations<sup>24</sup>. Both methodologies used to measure efficiency give approximately the same estimation; however, this subject requires further research.

Based on the findings presented above, I conclude that the CD-ROA is able to explain the apparently high price paid by investors at

this IPO which made an investment banker exclaim that “deals have started trading on best-case scenarios”. This approach shows that the success of Gilead's IPO is not due to overpricing but recognition of the value added by two facts not being considered by the traditional valuation method, the passive NPV approach. Those facts are, on one hand, that this firm is under a creative destruction process, which gives it an expectation of becoming the next monopolist, and, on the other hand, it has a growth option which gives it flexibility to make additional investments only in the case of success.

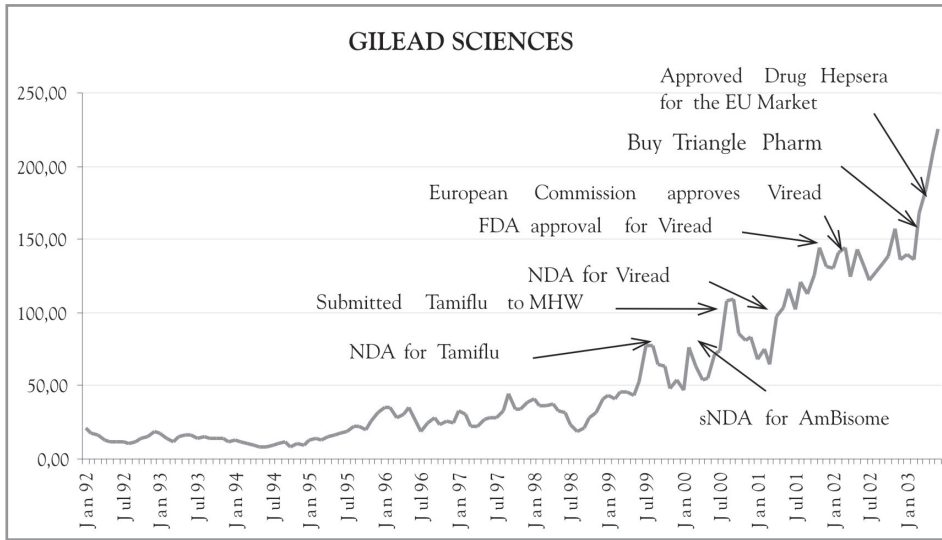

This approach also accounts properly for the probability of preemption by any competitor, in addition to other determinants of the value such as the characteristics of the industry which gives the distribution of the jump size, and the scrap value in case of preemption. Hence, all cases, not only best-case scenarios, are considered to estimate the value of this firm.

Furthermore, history will prove Gilead's investors were right. In April, 2001, this firm applied for an FDA approval for its antisense drug Viread, after successful clinical trials proving that it is effective against HIV/AIDS. The approval came in December that year. Later, in 2002, the EU approved its sale in Europe as well. Annual revenues from this drug are estimated around \$500 millions for 2003. Gilead's stock price has soared since its IPO from \$20.25 to \$225.56<sup>25</sup> in 2003, as can be seen in the following Figure.

<sup>24</sup> These estimations have a 95% confidence level. The estimation errors are reported in Appendix A Exhibit 10.

<sup>25</sup> This price was adjusted for splits. One share of Gilead in 1992 is equivalent to four shares in 2003.

**Figure 2**

As for the defeated companies, they had the choice to participate in a new technological race to discover another “drastic innovation” or leave the market. In the case of Gilead’s challenger, Isis, considered the “Microsoft of biotechnology” in the nineties, it has concentrated all its efforts

in a drug to fight cancer called Affinitak; however, news announcing that clinical trials have failed made the stock price fall in 2003. Some other relevant news and its effect on the Isis’ stock price are shown in Figure 3:

**Figure 3**  
Isis Pharmaceuticals Stock Price

The other two firms which started in the same race, AVI BioPharma and Hybridon, only managed to become public by 1997 and 1998, respectively. Although AVI BioPharma, founded as AntiVirals Inc, was the oldest of all antisense firms, after more than twenty years, its research has produced poor results with only four patents by 2003, compared to 554 of Isis and 106 of Gilead. In 1997, its founder, Dr. Summerton, was forced to resign as CEO and a new management came in, licensed new technologies, and now it has completed Phase II for Resten-NG, an antisense drug against Restenosis<sup>26</sup> as well as for Avicine, a therapeutic cancer vaccine<sup>27</sup>.

The fourth firm, Hybridon, is using another three technologies additional to antisense: Synthetic DNA, Cyclicon, and Immunomodulatory Oligonucleotide compounds. Their recent results are based on this last technology and are mainly focused on cancer. In conclusion, as it is predicted by the CD-ROA, all three of Gilead's challengers have decided to move on to new technological races, either by using new technologies different from antisense or by aiming to discover different kinds of drugs, - mainly drugs to fight cancer.

## Conclusions

In general, the value of biotech companies appears to be overpriced only in terms of traditional valuation methods such as the passive NPV approach which fails to account for drivers of value in highly innovative industries such as a growth option these companies may exercise in case of success innovating and the expectation of monopolistic market power if the innovation is drastic in the way described

by the Creative Destruction - Real Options Approach.

In this paper I apply the CD-ROA to the valuation of Gilead Sciences Inc., considering two different cases depending on the way efficiency of its research is measured. Results show that the value of Gilead should have been between \$286-289 millions. Gilead's investors paid 35% more than the offer price, a market value of \$289.6 millions, close to the previous two estimations<sup>28</sup>. Both methodologies used to measure efficiency give approximately the same estimation; however, this subject requires further research.

Based on the findings presented above, I conclude that the CD-ROA is able to explain the apparently high price paid by investors at this IPO which made an investment banker exclaim that "deals have started trading on best-case scenarios". This approach shows that the success of Gilead's IPO is not due to overpricing but to recognition of the value added by two facts not being considered by the traditional valuation method, the passive NPV approach. Those facts are, on one hand, that this firm is under a creative destruction process, which gives it an expectation of becoming the next monopolist, and, on the other hand, it has a growth option which gives it flexibility to make additional investments only in case of success.

This approach also accounts properly for the probability of preemption by any competitor, in addition to other determinants of the value such as the characteristics of the industry which gives the distribution of the jump size, and the scrap value in case of preemption. Hence, all cases, not only best-case scenarios, are considered to estimate the value of this firm.

<sup>26</sup> Restenosis occurs when the arteries opened up by angioplasty become blocked again. Like cancer, restenosis involves abnormal cell division (The Register Guard, 2001).

<sup>27</sup> AVI BioPharma, 10k Report, 2002.

<sup>28</sup> These estimations have a 95% confidence level. The estimation errors are reported in Appendix A Exhibit 10.

**EXHIBIT 1**  
**Strategies for the development of drugs for nucleic acid-based therapeutics**

Technology	Description	Therapeutical Target	Firms
<b>Antisense</b>	Antisense compounds are oligonucleotides. That is, they are short strings (oligomers) of the nucleotides that constitute either DNA or RNA. Their therapeutic potential arises from the fact that these antisense oligonucleotides contain nucleotide sequences that are complementary to specific mRNA sequences, and can block the translation of the mRNA to protein.	Viral infections Inflammatory diseases Cancer therapy	Isis Pharmaceuticals Lynx Therapeutics Gilead Sciences Anti Virals, Inc Hybridon, Inc Enzo Biochem Hoffman-LaRoche Amgen Genta Incorporated
<b>Triplex</b>	The potential for Triplex Technology was first realized at about the same time that Watson and Crick discovered the double helix of DNA, back in the 1950s. Like antisense, triplex technology ultimately prevents the expression of an gene to its protein. But whereas antisense blocks the translation of protein from RNA, triplex technology inserts a third strand of DNA into the target gene to prevent the initial formation of the mRNA, the process known as transcription.	Cancer Viral infections Inflammatory diseases - rheumatoid arthritis	Triplex Pharmaceuticals MicroProbe Corporation
<b>Ribozyme</b>	Ribozymes are unique compounds that are molecules of RNA having enzymatic properties. These catalytic molecules will bind to specific sequences on mRNA and cleave it so that it is no longer functional.	Cancer Chronic viral infections Inflammatory processes autoimmune diseases Rheumatoid arthritis Organ transplant rejection	Ribozyme Pharmaceuticals Immusol, Inc Johnson & Johnson

### Notes

\*In 1995 fiscal year changes from March 31st to December 31st. In Years 1993-1996 fiscal year ended in March 31st.

On July 29, 1999, The company entered into a business combination with NeXstar

Pharmaceuticals, Inc. (“NeXstar”). The business combination has been accounted for as a pooling of interests and our historical consolidated financial statements for all years prior to the business combination have been restated in the accompanying consolidated financial statements to include the financial position, results of operations and cash flows of NeXstar.

Pooling of interests method is used in limited situations in which shares of stock in the two companies are exchanged.
